### Motivation

Given: a (possibly unknown) nonlinear system

$$\dot{x} = f(x)$$
.

Extended Dynamic Mode Decomposition:<sup>2</sup> seeks y = h(x), matrix A with linear dynamics

$$\dot{y} = Ay$$
.

▶ To not lose information: want *h* one-to-one (1-1). Then

$$x(t) = h^{-1}(y(t))$$
  
=  $h^{-1}(e^{At}h(x_0)).$ 

► Such 1-1 linearizing maps h have also been called Koopman embeddings, faithful linear representations (Mezić 2021).

<sup>&</sup>lt;sup>2</sup>Williams, Kevrekidis, and Rowley. J Nonlinear Science (2015)

### Main issue and question

To avoid practical issues: want h at least continuous.

**Main issue:** continuous 1-1 linearizing h **do not exist** in general.

Main question: when do they exist and when do they not?

## When do Koopman embeddings exist?

Positive results (sufficient conditions)

Negative results (necessary conditions)

A counterexample for multiple isolated equilibria

### When do Koopman embeddings exist?

Positive results (sufficient conditions)

Negative results (necessary conditions)

A counterexample for multiple isolated equilibria

### Some positive results

Continuous 1-1 linearizing y = h(x) always exists:<sup>3</sup>

- near a hyperbolic equilibrium or limit cycle (Hartman-Grobman, Floquet);
- on the basin of any exponentially stable equilibrium or limit cycle (Lan-Mezić 2013, K-Revzen 2021);
- On the basin of ANY asymptotically stable equilibrium, not necessarily exponentially stable / hyperbolic (K-Sontag 2025)!

 $<sup>^{3}</sup>$ There are also  $C^{k}$  versions of all of these results.

## Global linearization for equilibria without hyperbolicity

Let  $x_*$  be asymptotically stable with basin B for

$$\dot{x} = f(x).$$

Assume f is continuous w/ unique trajectories defined for all time.

**Theorem** (K-Sontag 2025). There is a homeomorphism  $h \colon B \to \mathbb{R}^n$  such that y = h(x) satisfies

$$\dot{y} = Ay$$

and hence  $x(t) = h^{-1}(e^{At}h(x_0))$  for all  $t \in \mathbb{R}$ . And if  $f \in C^{k \ge 1}$ ,  $n \ne 5$ : h is a  $C^k$  diffeomorphism on  $B \setminus \{x_*\}$ .

### Remarks

- $\triangleright$  Exponential stability / hyperbolicity of  $x_*$  is not needed.
- ▶ Proof relies on solutions to Poincaré conjecture (Smale, Perelman, Freedman). In fact:

**Proposition** (K-Sontag 2025). The  $C^k$  statement for n = 5 in last theorem is true  $\iff$  the smooth 4-D Poincaré conjecture is true.

**Proposition** (K 2025). In the last theorem, if the vector field  $f_p$  depends continuously on parameter  $p \in P$ , there is a continuous family  $h_p : B \to \mathbb{R}^n$  of linearizing homeomorphisms if either (i) n > 5 and dim P = 1 or (ii) n < 4.

Proof of latter relies on corollary of:

**Theorem** (K 2025). The space of proper  $C^{\infty}$  Lyapunov-like functions on  $\mathbb{R}^n$  is path-connected and simply connected if  $n \neq 4, 5$  and weakly contractible if n < 4. (Same for space of  $C^{k \geq 1}$  GAS vf)

### When do Koopman embeddings exist?

Positive results (sufficient conditions)

Negative results (necessary conditions)

A counterexample for multiple isolated equilibria

### Some negative results

Assume a connected state space to avoid trivialities. Then

$$\dot{x} = f(x)$$

does **not** have a continuous 1-1 linearizing y = h(x) if **either**:

- there is a non-global compact attractor (K-Arathoon 2023), or
- ➤ all forward trajectories are precompact, and there are ≥ 2 but at most countably many omega-limit sets, e.g., multiple isolated equilibria (Liu-Ozay-Sontag 2023, 2025).

On the other hand, on the subject of multiple isolated equilibria...

### When do Koopman embeddings exist?

Positive results (sufficient conditions)

Negative results (necessary conditions)

A counterexample for multiple isolated equilibria

### Smooth 1-1 linearization despite multiple isolated equilibria

If we drop the assumption that forward trajectories are precompact, then (another positive result):

**Theorem** (Arathoon-K 2023). For any n > 1 there is a smooth vector field on  $\mathbb{R}^n$  with any given finite number of isolated equilibria such that there exists a smooth 1-1 linearizing y = h(x).

In fact, h is a smooth embedding w/ linear (left) inverse  $h^{-1}$ !

This theorem gives a family of strong counterexamples to an oft-repeated claim (cf. SIAM DS 2023 debate).

### Example

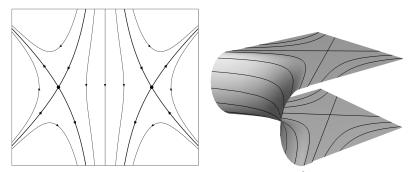

Figure: Smoothly embedding a nonlinear system on  $\mathbb{R}^2$  with two isolated equilibria as an invariant subset of a linear system on  $\mathbb{R}^3$ .

### When do Koopman embeddings exist?

Positive results (sufficient conditions)

Negative results (necessary conditions)

A counterexample for multiple isolated equilibria

# Where is the boundary between the positive and negative results?

We have now seen a variety of necessary conditions and sufficient conditions on

$$\dot{x} = f(x)$$

for a continuous 1-1 linearizing y = h(x) to exist.

**Fundamental question:** what are necessary **and** sufficient conditions on *f* for such an *h* to exist?

### Preamble to answering the fundamental question

Assume a connected state space to avoid trivialities.

- ▶ We can answer the fundamental question for any continuous f with unique trajectories defined for all time if there is at least one compact attractor.
- ▶ Recall there does not exist such an h if there are  $\geq 2$  such attractors, or even a single non-global compact attractor (K-Arathoon 2025).

► Remains to consider case of a global compact attractor (can also restrict to basin of local attractor to apply next result).

### Torus preliminaries

The *m*-torus  $T = T^m$  is Lie group isomorphic to  $(\mathbb{R}/\mathbb{Z})^m$ , vectors w/m real entries but w/m addition defined elementwise modulo 1.

A **torus action** on a space S is a map  $\Theta \colon T \times S \to S$  satisfying  $\Theta^{\tau_1 + \tau_2}(s) = \Theta^{\tau_1} \circ \Theta^{\tau_2}(s)$  for all  $s \in S$  and  $\tau_1, \tau_2 \in T$ .

A 1-parameter subgroup of  $\Theta$  is a map  $\Phi \colon \mathbb{R} \times S \to S$  of the form  $\Phi^t(x) = \Theta^{\omega t}(x)$  for some  $\omega \in \mathbb{R}^m$ .

 $\Theta$  has **finite orbit types** if there are only finitely many subgroups  $H \subset T$  such that, for some  $x \in S$ ,

$$H = Fix(x) := \{ \tau \in T : \Theta^{\tau}(x) = x \}.$$

### Finishing the answer to the fundamental question

Assume f is continuous with unique trajectories defined for all time, so f generates a continuous flow  $\Phi \colon \mathbb{R} \times X \to X$ .<sup>4</sup>

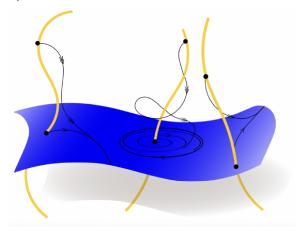

**Theorem** (K-Arathoon 2023). Assume there is a global compact attractor A (or restrict to the basin of a local attractor). Then a continuous 1-1 linearizing y = h(x) exists  $\iff$ 

- $lackbox{\Phi}|_{\mathbb{R}\times A}$  is a 1-parameter subgroup of a continuous torus action with finite orbit types, and
- ▶ A has continuous **asymptotic phase**  $P: X \rightarrow A$ .

Moreover, such h is automatically a proper topological embedding.

 $<sup>^4</sup>t\mapsto \Phi^t(x_0)$  is the unique solution of  $\dot{x}=f(x)$  satisfying  $x(0)=x_0$ .

### Asymptotic phase

**Asymptotic phase** means: for all  $x \in X$ ,  $t \in \mathbb{R}$ ,

$$P(\Phi^t(x)) = \Phi^t(P(x)).$$

 $\implies$  dist $(\Phi^t(x), \Phi^t(P(x))) \to 0$  as  $t \to \infty$ ; x is "asymptotically in phase with" P(x).

### Example: limit cycles

Previous theorem implies that dynamics on basin of limit cycle attractor admit a continuous 1-1 linearizing y = h(x) if and only if there is continuous asymptotic phase (w/ level sets "isochrons").

**Example.** Using polar coordinates  $(r, \theta)$  on  $\mathbb{R}^2$ , the system

$$\dot{r} = -(r-1)^3, \qquad \dot{\theta} = r$$

generates a smooth flow  $\Phi$  on  $\mathbb{R}^2 \setminus \{0\}$  with globally asymptotically stable limit cycle  $A = \{r = 1\}$ . Closed-form expression for  $\Phi$ 

$$\operatorname{dist}(\Phi^t(x), \Phi^t(y)) \not\to 0 \quad \text{as} \quad t \to \infty$$

for any  $x \notin A$ ,  $y \in A$ , so A does not have continuous asymptotic phase, so a continuous 1-1 linearizing y = -h(x) does not exist.

### What about smooth linearizations?

- Natural question: when does there exist a smooth 1-1 linearizing y = h(x) with smooth inverse  $x = h^{-1}(y)$   $(y \in image(h))$ ?
- Such an h is called a smooth embedding.
- ➤ So far, less satisfying answer in this case. But in particular, have the following necessary conditions:

**Theorem** (K-Arathoon 2023). Assume  $\dot{x} = f(x)$  has a global compact attractor  $A \subset X$  and is linearizable by a smooth embedding. Then:

- A is a smoothly embedded submanifold and normally hyperbolic,
- A has smooth asymptotic phase, and
- $lackbox{ }\Phi|_{\mathbb{R} imes\mathcal{A}}$  is a 1-parameter subgroup of a smooth torus action.

### Answer to fundamental question for compact invariant sets

If state space X is compact, can view A=X as a (trivial) compact attractor (with basin B=A=X). For this special case, we have:

**Theorem** (K-Arathoon 2023). Assume f generates a smooth (resp. continuous) flow  $\Phi$  and X is compact. Then there is a smooth (resp. continuous) linearizing embedding  $y = h(x) \iff \Phi$  is a 1-parameter subgroup of a smooth (resp. continuous w/ finite orbit types) torus action.

For X noncompact, can still apply this theorem by restricting to a compact invariant set.

### Surprising (?) examples with continuous 1-1 linearizations

Figure: For all of these flows, a continuous 1-1 linearizing y = h(x) exists (easy to see using preceding theorem).

### Some corollaries of preceding theorem

**Corollary** (K-Arathoon 2023). If X is a compact smooth manifold and f has at most finitely many equilibria, and if there exists a smooth linearizing embedding y = h(x), then

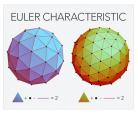

$$\underbrace{\chi(X)}_{\text{Euler characteristic}} = \#\{\text{equilibria}\} \ge 0.$$

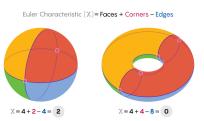

**Corollary** (K-Arathoon 2023). If X is an odd-dimensional compact smooth manifold and f has at least one isolated equilibrium, then there does not exist a smooth linearizing embedding y = h(x).

**Proof sketch.** Using previous theorem, Bochner's linearization theorem for fixed points of torus actions  $\implies$  the Hopf index of any equilibrium is +1. Apply the Poincaré-Hopf theorem to deduce the first corollary. Deduce the second corollary from the first using  $\chi(X)=0$  if X is an odd-dimensional compact manifold.

### A primer on the Euler characteristic<sup>5</sup>

Goes back to Francesco Maurolico (1537), Leonhard Euler (1758).

**Notation**:  $\chi(Y) := \text{Euler characteristic of } Y$ .

**Examples**: 
$$\chi(\bullet) = 1$$
,  $\chi(\mathbb{S}^1) = 0$ ,  $\chi(\mathbb{S}^2) = 2$ ,  $\chi(\Sigma_{\sigma}) = 2 - 2g$ 

 $\Sigma_g$  for g=1,2,3 (not linearizable by smooth embedding for g>1 if there is an isolated equilibrium).
